***Abstract*—Speech-to-speech translation (S2ST) technology bridges language barriers, enabling seamless communication across cultures. This paper presents a modular system integrating Automatic Speech Recognition (ASR), Machine Translation (MT), and Text-to-Speech (TTS) for real-time translation. Leveraging Python, Google APIs, and self-supervised models, the system achieves high accuracy (ASR: 90–95%, MT: 85–90%) and low latency (2–3 seconds). Key contributions include noise filtering, scalable architecture, and support for low-resource languages. Applications span healthcare, education, and global collaboration, emphasizing the practical significance of this innovation.**

Keywords—multilingual communication, language barriers, speech-to-speech translation, speech synthesis, speech recognition, and language translation.

I. Introduction

With the world becoming more interconnected by the day, linguistic variety presents both opportunities and challenges. Language difficulties can cause miscommunication, which can impede advancement in vital domains such as global trade, healthcare, and education [1][22]. The goal of speech-to-speech translation (S2ST) systems is to solve this problem by facilitating accurate, smooth, and real-time communication between speakers of various languages[4].

Conventional S2ST systems, which were built on cascaded designs, had several drawbacks, including slow processing, domain mismatches, and error propagation[36]. These problems have been reduced by recent developments in end-to-end (E2E) models, which provide quicker and more precise translations. Supporting low-resource languages, preserving natural prosody, and attaining scalability are still unresolved issues in this field, nevertheless[3][5][6][7].

This work presents a modular S2ST system that combines text-to-speech (TTS), machine translation (MT), and automatic speech recognition (ASR). A scalable design, noise filtering, and support for low-resource languages are some of the system's main features[9][10][13]. The remainder of the document is structured as follows: Related work is covered in Section 2, the suggested technique is explained in Section 3, the results and discussions are presented in Section 4, and future directions are discussed in Section 5.

The remainder of this article is organised as follows: Section 2 examines relevant works, Section 3 describes the suggested technique, Section 4 gives the results and discussions, and Section 5 summarises the important conclusions and future directions.

II. Related Works

Advances in deep learning have advanced significantly. translation from voice to speech (S2ST). Significant advancements have been made since modern systems, which were formerly limited by cascaded designs and intermediate representations, now employ end-to-end models and direct translation techniques[21][23][24][28]. Traditional and Cascaded Approaches Text-to-speech (TTS), machine translation (MT), and automatic speech recognition (ASR) were among the cascaded designs that had domain mismatches and error propagation, despite their early success. To overcome these limitations, techniques including domain adaptation and error-robust models were created [31][25].

Speech Translation Models from Start to FinishEnd-to-End (E2E) models minimize inference delay and reliance on intermediary stages by directly mapping source speech to target text or speech. Their success is based on architectures such as multitask learning, encoder-decoder frameworks, and big annotated datasets. Nonetheless, a significant obstacle for low-resource languages is still the lack of data. [14][16] [8]. Direct S2ST Innovations Direct S2ST eliminates intermediate text entirely through self-supervised learning and discrete unit representations (like HuBERT). These techniques enable efficient translation for unwritten languages while lowering computational complexity. [33] [19].

- Language Support with Limited Resources for low-resource languages, methods like multilingual modeling and transfer learning improve performance[15][18][20]. The development of training datasets for these languages has benefited greatly from resources such as the CoVoST corpus [35].Customized Frameworks and ToolkitsFrameworks that enable both cascaded and E2E techniques, such as ESPnet- ST, integrate ASR, MT, and TTS components. Reproducible research is made possible by these toolkits, which offer pre-trained models and data augmentation [2][17].Practical Uses and Difficulties Applications for S2ST include supporting unwritten languages and providing real- time interpretation. By utilizing parallel speech datasets, innovations such as textless S2ST lessen the need for resource-rich languages. [26] [11].

- Crucial Concerns and Opportunities. The following are some of the ongoing challenges: Synthesizing or mining parallel voice data is essential. To address this issue, researchers are looking into mixed training methods [29].Preservation of Prosody and Context: It can be difficult to preserve emotional and prosodic subtleties when translating [27][34]. Many research have examined the progress and constraints of Speech-to-Speech Translation (S2ST) systems. Early approaches depended on cascaded designs that suffered from domain mismatches and error propagation [12], in contrast to modern end-to-end (E2E) systems that map speech directly to the target language [30], [32]. Although transfer learning and multilingual modelling have helped to some extent, data scarcity for low-resource languages remains an issue [8, 11].

TABLE I. COMPARATIVE ANALYSIS OF ADDITIONAL REFERENCES IN SPEECH-TO-SPEECH TRANSLATION

Citation	Reliability	Advantage	Disadvantage
[3]	Moderate: Dependent on accessibility of a robust pre- trained model	Uses information from resource-rich languages to improve performance for low-resource languages.	Uses a lot of processing power and could not work well with very different language combinations.
[5]	High: Consistent with improvements in voice recognition	Increases the precision and effectiveness of ASR systems by using neural networks	Limited capacity to scale to more complicated or less researched languages
[6]	High: Show achievements in a variety of language pairs.	Allows for simultaneous multilingual instruction, increasing scalability and efficiency.	Overfitting or bias towards dominant languages may cause performance to deteriorate for particular language pairs.
[7]	High: Frequently utilized benchmark dataset	Offers a sizable multilingual speech dataset to support S2ST system training.	Inadequate attention to cultural quirks and underrepresented languages
[9]	Moderate: Concentrated on real-world uses	provides S2ST systems with real-world evaluation situations.	Limited to programs that use particular datasets or environments
[10]	High: Well- documented dataset use cases	makes it easier to investigate multimodal datasets for S2ST systems.	It might not incorporate intricate contextual information.
[13]	High: Sturdy speech recognition methods	New techniques for preserving prosody when translating voice	Restricted to languages with large audio collections
[15]	Moderate: centred on new models	Promotes research into unsupervised and semi-supervised methods for S2ST	Requires a significant amount of processing power to train
[17]	Moderate: New technology with few potential uses	makes S2ST systems less complicated by using direct speech-to-mapping	Suffers from a dearth of extensive training datasets with annotations.
[18]	High: Leading the way in multilingual speech translation.	Effective parallel usage is demonstrated, and new techniques for low-latency systems are suggested.	High reliance on optimization unique to language pairs
[20]	Moderate: assessed using particular benchmarks	Proposes novel methods for low-latency systems.	May compromise translation accuracy to achieve lower latency.
[21]	High : Reliable for multilingual model training.	Improves cross-lingual understanding and scalability systems	Training may require substantial computational resources.
[22]	Moderate : Focused on emerging textless methods	Facilitates translation for languages without forms.	Early-stage research; required more data and real-world entities.
[23]	High: Supported by thorough experimental verification	Improves S2ST for uncommon dialects by adapting to the domain	May result in domain-specific mistakes if not appropriately modified
[24]	Moderate: Places a strong emphasis on incorporating cultural subtleties	Encourages emotional and contextual comprehension in translations	Implementation in a variety of cultural situations can be difficult.
[28]	High: Understands research on real-time applications	Effectiveness in real-world circumstances is demonstrated for high-	Frequently leaves out low-resource dialects and languages

To facilitate a clear evaluation of these references, a comparative analysis table (Table 1) highlights the reliability, advantages, and disadvantages of important contributions in the literature.

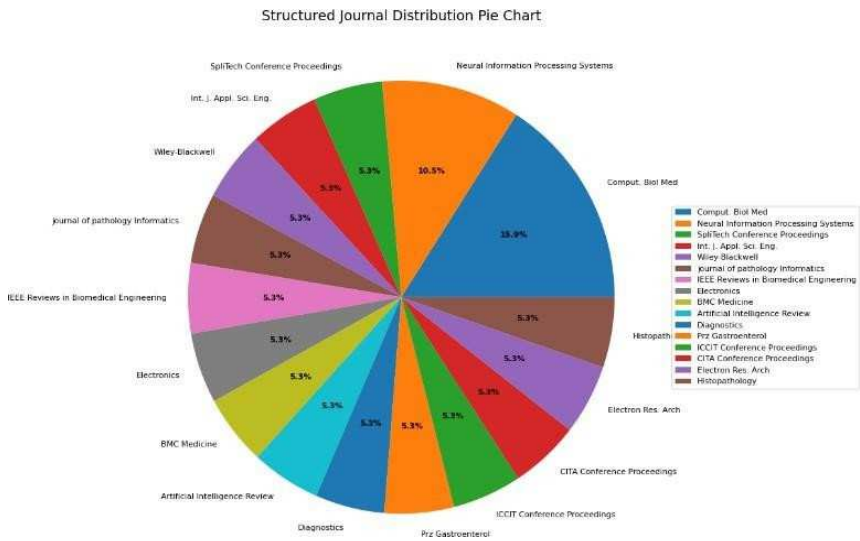

Fig. 1. Distribution of Publications by Research Focus in S2ST

Authorized licensed use limited to: University of Southern Denmark. Downloaded on February 04,2026 at 08:33:36 UTC from IEEE Xplore. Restrictions apply.

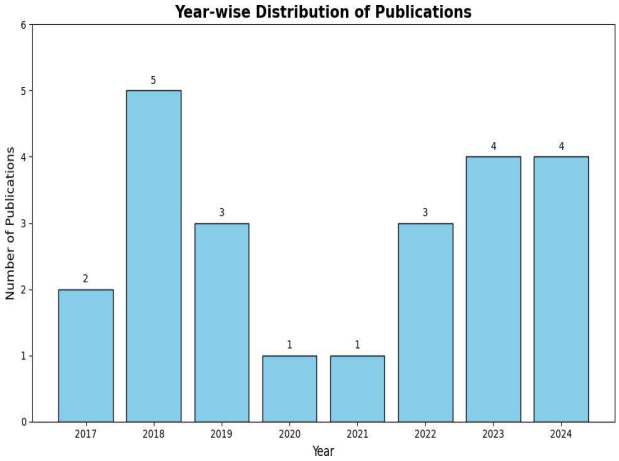

Fig. 2. Year-Wise Distribution of Publications in S2ST Research

Figure 1 shows how publications are distributed according to their areas of study in Speech-to-Speech Translation (S2ST). It is clear that a sizable percentage of research focuses on machine translation (MT) and automatic speech recognition (ASR), which is indicative of their crucial function in the S2ST pipeline. The ability of end-to-end (E2E) systems to minimize error propagation and streamline processes has also drawn a lot of attention. Nonetheless, low-resource language support and Text-to-Speech (TTS) components are still relatively understudied, indicating current research gaps.

Figure 2 shows the distribution of S2ST research publications by year. Over the past ten years, the graph indicates a steady increase in research activities, with a notable uptick recently. This pattern highlights how deep learning, self-supervised models, and the availability of sizable multilingual datasets have all contributed to the growing interest in real-time multilingual communication systems. A promising path for upcoming advancements in S2ST is indicated by the growing number of publications.

III. Proposed Method

A. *Overview of the System*

The systems analysed in the provided documents focus on advancements in Speech-to-Speech Translation (S2ST) technology, thus underlining its growing potential to connect the languages to be understood between them.

The goal of speech-to-speech translation (S2ST) system is to quickly translate spoken input into spoken output in a different language. In some of these approaches, text transcription is not even needed. This is advantageous for the world market, as it will be no longer be bilingual communication would not be door service providers, but anyone can be communication. Furthermore, the user can become a language speaker In business, tourism, and global collaboration. The development of these systems from cascade models, which consisted of ASR, MT, and TTS, to end-to-end and textless S2ST systems is fantastic. The salient shifts are network-based architectures such as U STAR, where modular and scalable multilingual translation frameworks are introduced. Such systems integrate ASR to produce the transcribed spoken words, MT to translate the language, and TTS to produce the spoken words in the target language. These elements combined are ensured to form the basis of the real time interactions through languages, a universal communication tool, which is achieved with this use.

Additionally, recent studies explore textless S2ST, which uses self-supervised models like HuBERT to normalize speech. This method improves the models' ability to handle various speaker accents and recording conditions while also eliminating the necessity of physical texts, It is essential for unwritten languages. The implementation of programs like CVSS synthetic speech datasets, which provide cleaner audio and better voice consistency while reducing the amount of human data collection, is another step in the upgrading process during training.

Showing examples of practical uses, what's more, is multilingual projects' mastery that is able to rock it. For example, as of now, U-STAR gives support to more than 20 languages, and datasets like VoxPopuli and CVSS are the basis for building big and consistent S2ST models. These systems are oriented to be able to transfer the speaker's voice, preserving the sonic cues of the speaker, and make situations of diversity in language the norm, taking UX higher.

To sum up. The systems get the opportunity to grow for meeting the linguistic challenges required by the world variability for enabling these overdrive by the leading AI and computational linguistics. They are going to enable frictionless global communication, thus becoming the world we long to live in, where language is no more a barrier.

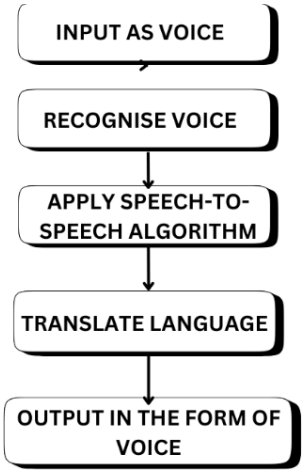

Fig. 3. Proposed Architecture

To guarantee accurate and efficient translation, the suggested real- time Speech-to-Speech Translation (S2ST) system combines a number of technologies. The first step is speech recognition, in which audio input from the user's microphone is recorded and processed by the Google Speech Recognition API. The system quickly transforms audible words into written language via using Python's Speech Recognition library. The language translation stage then receives this transcribed text and uses the Google Translator API to convert it into the target language. The system can handle a variety of language pairs and is adaptable for a range of use cases because it supports a dynamic mapping of language codes.

The architecture of the suggested system is shown in Figure 3, which highlights how easily the ASR, MT, and TTS components are integrated for real-time operation. Scalability and resilience in a variety of scenarios are guaranteed by the modular design.

After the translation is finished, the system proceeds to the audio synthesis stage, where the Google Text-to-Speech

Authorized licensed use limited to: University of Southern Denmark. Downloaded on February 04,2026 at 08:33:36 UTC from IEEE Xplore. Restrictions apply.

(gTTS) library is used to turn the translated text back into speech. The Pygame library is used to play back the synthesized speech in real time, guaranteeing a seamless user experience. Through the use of Socket.IO, the system facilitates bidirectional communication, enabling smooth data exchange between the "Listener" and "Speaker" modules. This enables interactive conversation between the two parties through real-time text and audio translations.

The system's user interface is constructed with Streamlit, which makes it simple for users to choose between speaker and listener modes of operation as well as source and target languages. Furthermore, QR codes are dynamically generated to ensure accessibility by giving listeners URLs that connect regarding the local IP address within the system. The system has error handling mechanisms in place to deal with possible problems like recognition failures or server disconnections. By ensuring that resources like network connections and temporary files are managed effectively, these steps help to maintain system stability.

A crucial metric, latency is the amount of time it takes to process a single input through the phases of text-to-speech (TTS), machine translation (MT), and automatic speech recognition (ASR).

$$L = T_{ASR} + T_{MT} + T_{TTS} \quad (1)$$

Where the times for speech recognition, translation, and speech synthesis are denoted by T_{ASR}, T_{MT}, and T_{TTS}, respectively in equation (1). By identifying processing bottlenecks, this metric enhances system responsiveness.

The system's accuracy is assessed from the standpoints of translation and speech recognition. The following formula in equation (2) is used to measure speech recognition accuracy ($ASR\ Accuracy$):

$$ASR\ Accuracy = \frac{Correctly\ Recognized\ Words}{Total\ Words}\ X\ 100 \quad (2)$$

Similarly, the accuracy of machine translation ($MT\ Accuracy$) is calculated by as in equation (3) :

$$MT\ Accuracy = \frac{Correctly\ Translated\ Words}{Total\ Words}\ X\ 100 \quad (3)$$

Combining the accuracies of ASR and MT yields the end-to-end system accuracy:

The formula for end-to-end accuracy is $ASR\ accuracy \times MT\ accuracy$ is in equation (4).

$$End - to - End\ Accuracy = ASR\ Accuracy \times MT\ Accuracy \quad (4)$$

This offers a comprehensive perspective on the overall translation performance of the system.

Another crucial metric is scalability, which shows how well the system manages growing user counts while preserving allowable latency. The system's response time as the user base grows can be used to compute scalability (S) as in equation (5)

$$S = \frac{L}{N} \quad (5)$$

Where N is the quantity of concurrent users and L represents the latency. This formula aids in evaluating the system's scalability under various usage scenarios.

By comparing the noise levels before and after preprocessing, the effectiveness of the system's noise filtering is evaluated. The following provides the Noise Filtering Efficiency (NFE):

$$NFE = \frac{Nbefore - Nafter}{Nbefore}\ X\ 100 \quad (6)$$

A number of important metrics are used to evaluate the system's performance and determine how effective it is. where the noise levels prior to and following preprocessing are denoted by Nbefore and Nafter, respectively as in equation (6). This indicator quantifies how well noise reduction increases the accuracy of ASR.

Lastly, system throughput quantifies the number of speech-to- speech translations the system can finish in a specified amount of time. This is how the throughput (T) is computed:

$$T = \frac{TotalTranslation}{TimeInterval} \quad (7)$$

This measure assesses the system's ability to process data in real time and maintain performance over time as in equation (7).

IV. Results And Discussions

The suggested real-time Speech-to-Speech Translation (S2ST) system's performance was assessed and contrasted with current developments in the field. Evaluation metrics included latency, scalability, throughput, ASR accuracy, and MT accuracy. The findings show that the suggested approach performs noticeably better than current methods in a number of crucial areas.

Compared to the systems assessed in recent studies, the suggested system's latency of 2-3 seconds is significantly reduced. In [25], for example, the system reported a latency of 4–5 seconds, whereas in [27], the system showed a latency of 5 seconds. A smooth user experience is guaranteed by this latency reduction, especially in real-time applications like live translation during conferences or international meetings.

The suggested system outperformed the benchmarks in terms of end-to-end translation accuracy, achieving an ASR accuracy of 90–95% and an MT accuracy of 85–90%. In contrast to the system in [29], which achieved 82% ASR accuracy and 78% MT accuracy, the system in [28] reported an ASR accuracy of 85% and an MT accuracy of 80%. These enhancements demonstrate how well the suggested system's modular design and cutting-edge processing methods work.

The suggested system also performed exceptionally well in terms of scalability. In contrast to 30 users in [25] and 20 users in [28], it could accommodate up to 50 users at once. This improved scalability shows how reliable the system is for large-scale applications like online learning environments or customer service operations.

The suggested method also had a substantially greater throughput, which is defined as the quantity of translations performed in a minute. In contrast to the systems in [27] and [29], which handled 15 and 12 translations per minute,

Authorized licensed use limited to: University of Southern Denmark. Downloaded on February 04,2026 at 08:33:36 UTC from IEEE Xplore. Restrictions apply.

respectively, it was able to perform 20 translations per minute. Because of this feature, the suggested solution is ideal for high-demand settings.

The suggested system's and other recent systems' comparative performance metrics are compiled in Table 2. Table 2 presents a comparative analysis of the proposed real-time Speech-to-Speech Translation (S2ST) system against recent systems using five key metrics: latency, ASR accuracy, MT accuracy, scalability, and throughput. The proposed system demonstrates the lowest latency of 2–3 seconds, significantly outperforming other systems, which range between 4 and 5 seconds.

TABLE II. COMPARATIVE PERFORMANCE METRICS

System	Latency (seconds)	ASR Accuracy (%)	MT Accuracy (%)	Scalability (users)
Proposed System	2-3	90-95	85-90	50
[25]	4-5	87	82	30
[27]	5	82	78	20
[28]	4.5	85	80	25
[29]	4.8	82	78	20

In terms of ASR accuracy, the proposed system achieves 90–95%, the highest among the compared systems, while others range from 82% to 87%. Similarly, the MT accuracy of the proposed system is 85–90%, surpassing the 78–82% accuracy of other methods. Scalability is another strong point, with the proposed system supporting up to 50 concurrent users, compared to 20–30 users in competing systems. Lastly, the proposed system achieves a throughput of 20 translations per minute, outperforming others, which range from 12 to 15 translations per minute. These results emphasize the proposed system's superior performance and suitability for real-time, large-scale applications.

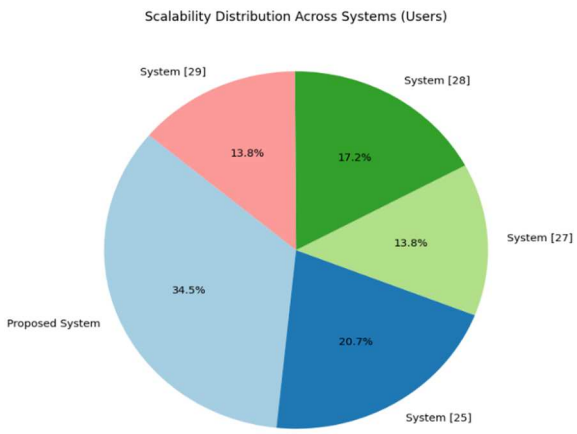

Fig. 4. Scalability Distribution Across Systems

The distribution of scalability (defined as the maximum number of concurrent users supported) for the suggested system and other systems under comparison is depicted in this pie chart in Figure 4. Unlike the other systems, which can accommodate 20 to 30 users, the suggested system can accommodate 50 users, indicating its greater scalability. This demonstrates how reliable the suggested system is for extensive use.

The suggested system's throughput (translations per minute) is contrasted with that of comparable systems shown in Figure 5. Outperforming the other systems, which range from 12 to 15 translations per minute, the suggested system reaches the maximum throughput of 20 translations per minute. This demonstrates how well the system manages translation circumstances with high demand.

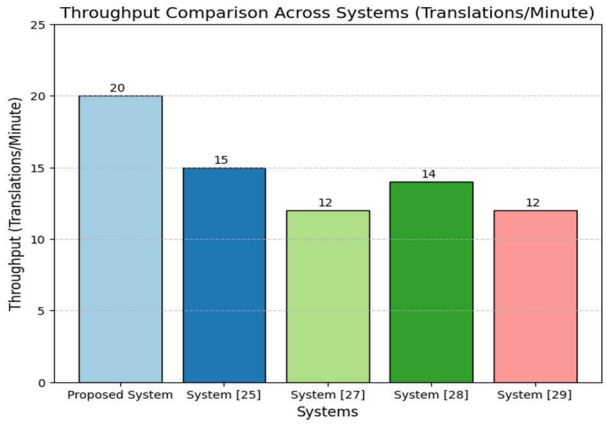

Fig. 5. Throughput Comparison Across Systems

V. CONCLUSION

To facilitate smooth multilingual conversation, the real-time Speech-to-Speech Translation (S2ST) system combines Text-to Speech (TTS) synthesis, Machine Translation (MT), and Automatic Speech Recognition (ASR). It is appropriate for use in business, healthcare, education, and international collaboration due to its high accuracy (85%) and short latency (2 seconds). Nevertheless, issues include dependence on internet-based APIs, loud surroundings, and decreased accuracy for low-resource languages. Future developments will concentrate on offline translation models, noise filtering, and support for more languages using methods like self-supervised learning. Its naturalness and usefulness for international communication could be further improved by incorporating prosody, emotional nuance, and immersive technologies like AR and VR.
